Understanding Problem statement

Datatype - Multispectral and Multi-temporal images of crop data of 2 years.

Task - Extract Crop cycle Parameters.

Output - Date of Sow and Harvest , Number of Harvest for each pixel.

Organisers

MHRD

MIC

ANTRI

Persistent

ISRO

Platinum Partner

Assumptions

1. Month of the image will be given with input image.
2. Each pixel represent a crop field.
3. Low pixel density means no crop and high pixel density means dense crop.
That is lower the value of pixel more will be the density of the crop.

Dataset analysis

We calculated mean value of all the pixels for each image and plotted it against months. The trend for the harvesting & sowing for year 2017 & 2018 are as below :-

Approaches

- Deep Neural Networks for Fine tuning.
 - a. Aim was to predict month from Image.
 - b. Inception model used with Dense(1024)->Dropout(0.4)->Dense(12) as additional layers.
 - c. Each Image cropped in 100 equal parts and ImageDataGenerator used to augment the data.
 - d. Trained for 40 epochs.
 - e. Overfitting led to poor results.
- Decompression of tif images
 - a. Various softwares were used to get high resolution RGB image.

Working method

- Mean Calculation method
 - Mean of RGB values of each pixel are calculated.
 - The mean gives an idea of which crop season is going on.
 - That gives a threshold value to calculate a pixel's information.
 - Higher the mean -> Lower the crop density
 - Lower the mean -> Higher the crop density.
